1 Introduction

The research of dust detonation is very important both in weapons and industrial hazards. There is a lot of damage of dust detonation in the industry security. Every year many people died of the dust detonation in the world such as the coal dust and the aluminum dust explosion. The accident of wheel hub work shop happened in KunShan China August 2014 was a serious dust explosive disaster. There are 75 people died and 260 people injured in the accident. The RDX is a common explosive and it’s very easy ignited. The Al is light, cheap and has much energy as a metal. So it has much significance to study the mechanisms and effect of the detonation of two-phase.

The problem of two-phase detonation is very complex. There are three propagation regimes\cite{1}: the Pseudo-Gas Detonation, the Single-Front Detonation and the Double-Front Detonation. The production of the different detonation structures is due to the difference of heat release process. For this paper, we investigate the difference of the Single-Front Detonation and the Double-Front Detonation. We use the two-phase model to simulate the detonation with CE/SE method. The detonation of RDX particles in air, aluminum particles in air and RDX and aluminum particles in air together are all simulated.

2 Model

The two-phase model is used in the simulation. And also we purpose the particles are spherical, the initial diameters are same, the temperature of every particles is balance, the interaction of particles is ignored, the energy of chemical reaction is absorbed by gas, the component of gas are homogeneous, the frictional force between particles and the wall is ignored, the radiation between particles and gas is ignored, both the solid phase and gas phase satisfied the equation.

Gas equation:

\[
\frac{\partial \rho_1 \varphi_1}{\partial t} + \frac{\partial \rho_1 \varphi_1 u_1}{\partial x} = I_{d2} + I_{d2a}
\]

\[
\frac{\partial \rho_1 \varphi_1 u_1}{\partial t} + \frac{\partial \left( \rho_1 \varphi_1 u_1^2 + p \right)}{\partial x} = I_{d2} u_2 - F_{d2} + I_{d2a} u_{2a} - F_{d2a}
\]

\[
\frac{\partial \rho_1 (e_1 + 0.5u_1^2)}{\partial t} + \frac{\partial \varphi_1 u_1 \left( \rho_1 e_1 + 0.5 \rho_1 u_1^2 + p \right)}{\partial x} = -Q_{d2} + I_{d2} (e_2 + 0.5u_2^2) + I_{d2} q_2 - F_{d2} u_2 - Q_{d2a} + I_{d2a} (e_{2a} + 0.5u_{2a}^2)
\]

\[
+ I_{d2a} q_{2a} - F_{d2a} u_{2a}
\]

Solids equation:

\[
\frac{\partial \rho_1 \varphi_1}{\partial t} + \frac{\partial \rho_1 \varphi_1 u_1}{\partial x} = -I_{di}
\]
Zan Wen Tao

Numerical simulation of the suspended mixed RDX and Al

\[
\frac{\partial \rho_i \phi_i u_i}{\partial t} + \frac{\partial \rho_i \phi_i u_i u_j}{\partial x} = -I_{di} u_i + F_{di}
\]

\[
\frac{\partial \rho_i \phi_i (e_i + 0.5u_i^2)}{\partial t} + \frac{\partial \rho_i \phi_i (e_i + 0.5u_i^2)}{\partial x} = Q_{di} - I_{di} (e_i + u_i^2) + F_{di} u_i
\]

\[
\frac{\partial n_i}{\partial t} + \frac{\partial n_i u_i}{\partial x} = 0
\]

Component of gas equation:

\[
\frac{\partial \rho_i \phi_i y_i}{\partial t} + \frac{\partial \rho_i \phi_i y_i u_i}{\partial x} + \frac{\partial \rho_i \phi_i y_i y_j}{\partial y} = w_j
\]

State equation

\[
P = \rho RT \sum_{i=1}^{m} \frac{y_i}{w_i}
\]

In these equations, \(i = 2, 2a\) and the subscripts 1, 2 and 2a denote the variables of gas, RDX and Al. The variables are follows: \(\rho\) the density, \(u\) the horizontal velocity, \(v\) the vertical velocity, \(e\) the internal energy, \(P\) the pressure, \(\phi_i\) the volume fraction, \(I\) the ratio of mass of unit volume. There are seven component in gas which are \(O_2, N_2, CO, CO_2, H_2O, Al(g)\) and \(Al_2O_3(g)\). \(y\) is concentration, \(w\) is molecular weight of gram.

For the RDX, we use the model in Hong\(^2\), as follow:

\[
I_{d2} = \begin{cases} 0 & T_2 < T_m \\ \frac{Q_{d2}}{L} & T_2 \geq T_m \end{cases}
\]

\(T_m\) is the melting point of RDX, \(L\) is latent heat. The RDX particles move under the effect of shock wave and heat up because of the heat conduct. And it begin to be peeled after melt and break down in the high temperature.

For the Al, we use the model\(^3\), as follow:

\[
I_{d2a} = -nP_{2a} 4 \pi R^2 \frac{dR}{dt} \\
1 \frac{dR}{dt} = -\frac{1}{kd_0^m/\Phi^{0.9}}
\]

\(N\) is the number of particles in unit volume, \(R\) is the radius of particles, \(d_0\) is the initial diameter, \(\Phi\) is the fraction of \(O_2\), \(m = 1.75\).

\(F\) is the force that the gas to particles:

\[
F_{di} = \frac{n \pi R^2 C_d \rho_i \sqrt{(u_i - u_j)^2 + (v_i - v_j)^2 (u_i - u_j)}}{2}
\]

\(C_d\) is the drag force, \(Q\) is the conduct heat:

\[
Q_{di} = 4 n \pi R^2 \lambda T_i (T_1 - T_i)/(2R)
\]

\(\lambda\) is the heat conduct coefficient, \(Nu\) is the Nusselt number, \(q\) is the reaction power of unit mass. The metallic oxide will decompose to \(Al(g)\) and \(O_2\) when the temperature is higher than the boiling point\(^4\). So the temperature will keep below the boiling point.

### 3 Simulation

To check the correctness of the program, we simulate the two dust separately. For the density of RDX is 0.75kg/m\(^3\), the speed of the detonation wave is 1.899Km/s, the peak is 4.75MPa. S.Eidelman\(^5\) achieved the peak was 4.84MPa, Hong\(^2\) got the speed was 1.802Km/s and Dong\(^6\) got the speed was 1.916Km/s. For the density of Al is 0.304kg/m\(^3\), we achieve the parameter of the detonation wave is \(D = 1.63Km/s\), \(\rho_{Cl} = 2.43 Kg/m^3\), \(u_{Cl} = 673 m/s\), \(P_{Cl} = 2.04MPa\), \(T = 3800K\), \(P = 3.31MPa\). The experiment of A.J.Tulis\(^7\) achieved the speed is 1.65Km/s and result of literature\(^8\) is \(D = 1.63Km/s\), \(\rho_{Cl} = 2.48 Kg/m^3\), \(u_{Cl} = 681 m/s\), \(P_{Cl} = 1.91MPa\), \(T = 3800K\). The simulate result correspond to other researchers' very well.
In the simulation, $\rho_{\text{RDX}} = 0.565 \text{kg/m}^3$, $\rho_{\text{Al}} = 0.145 \text{kg/m}^3$. For $r_{\text{RDX}} = 10 \mu\text{m}$, Fig. 1(a) is the pressure of the detonation wave and the lines from left to right are in condition that $r_{\text{Al}} = 3.5 \mu\text{m}$, the RDX is only and $r_{\text{Al}} = 1 \mu\text{m}$ at the same moment. Fig. 1(b) is temperature of gas, Al and RDX for $r_{\text{Al}} = 3.5 \mu\text{m}$ and $r_{\text{Al}} = 1 \mu\text{m}$ at the same moment. The three lines on left are temperature of gas, Al and RDX for $r_{\text{Al}} = 3.5 \mu\text{m}$ and the three lines on right are temperature of gas, Al and RDX for $r_{\text{Al}} = 1 \mu\text{m}$. From the picture we can see when the radius of Al is small, the power of RDX can make the Al react rapidly and the time of exothermic differ small so that the wave only has one peak. The peak of the wave is far from the wave of RDX only. When the radius of Al becomes bigger, the two dusts exothermic at the different time, the two peaks of detonation wave are observed. The first crest is the reaction of RDX. From the picture we can see the reaction time of RDX is very short. And the second crest is Al. The peak of pressure of Al is smaller than RDX and the reaction time of aluminum is longer than RDX. The speed and the pressure of the double-front detonation are both smaller than that of the single-front detonation. But the reaction region of the double-front detonation is longer.

Table 1 is the parameters of detonation wave of different radius of Al. While the radius of Al becomes larger, the wave speed will smaller, however when the radius reach the limit, the wave speed will keep const that the maximum wave speed of the Al only at the same density. The pressure of the second
Zan Wen Tao

Numerical simulation of the suspended mixed RDX and Al

wave which is the peak of the second wave and the parameter of CJ point also become smaller with the radius of Al become larger. The CJ points are all behind the second wave.

Set the radius of Al as 3.5μm, the graphs of fig 3 are the pressure and temperature. The lines from left to right are in condition that the radius of RDX are 5μm, 7.5μm, 10μm, 12.5μm, 15μm, 17.5μm, 20μm. The pressure of front wave is higher with the radius. For r_{RDX} = 20μm, the two peak of wave is not obvious. When the radius becomes smaller, the
Numerical simulation of the suspended mixed RDX and Al

distance of the two waves become longer. The energy of RDX will warm up the Al, so the temperature of the wave will decrease. But with the Al exothermic, the temperature will trend to same.

4 Conclusion

In this letter, it simulates the detonation of RDX and aluminum particles in air alone. And the result fit the achievement of other researches very well. From the result it’s found that the CE/SE method is suitable to simulate the problem of multiphase detonation. With the program the two mixed dusts detonation is studied. The research is focused on the double-front detonation wave structure. We studied the relationship of the speed and peak of pressure of detonation wave with radius of Al and the effect of radius of Al. And quite satisfactory calculation results are obtained.
